I. INTRODUCTION

In a quantum many body (Monte Carlo) simulation of a Coulomb liquid it is often useful to have access to the low temperature pair Coulomb density matrix ρ . In the high temperature classical limit the *primitive approximation* $\rho_{\text{primitive}}$ becomes exact. Within Path Integral Monte Carlo (PIMC) of a many body system [1] in order to access the quantum regime with less imaginary time discretization error it is important to lower the temperature in the *pair-product inter-action*. The imaginary time t is related to the temperature T of the liquid by $t = \beta = 1/k_B T$ with k_B Boltzmann constant. The main ingredient to construct the pair-product inter-action is the pair density matrix. Starting from $\rho_{\text{primitive}}$ at a high temperature T_0 we can halve the temperature simply by squaring it [2, 3] (see also section IV.G of Ref. [1]). This lower temperature pair density matrix already possesses different properties than the primitive approximation. In position representation, on the diagonal

$$\left| \frac{\phi(\mathbf{r}_1, \mathbf{r}_2)}{k_B T_0} \right| = \left| \ln \left[\frac{\rho_{\text{primitive}}(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; 1/k_B T_0)}{\rho_0(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; 1/k_B T_0)} \right] \right| \xrightarrow{\mathbf{r}_1 \rightarrow \mathbf{r}_2} \infty, \quad (1.1)$$

where $\phi(\mathbf{r}_1, \mathbf{r}_2)$ is the pair Coulomb potential between particle 1 at $\mathbf{r}_1$ and particle 2 at $\mathbf{r}_2$. On the other hand we can reach the temperature $T_0 = T_n/n$ through the *continuum limit* sending $n \rightarrow \infty$ and $T_n \rightarrow \infty$. In this case we find

$$|P(\mathbf{r}_1, \mathbf{r}_2; 1/k_B T_0)| = \lim_{n \rightarrow \infty} \left| \ln \left[\frac{[\rho_{\text{primitive}}]^n(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; n/k_B T_n)}{[\rho_0]^n(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; n/k_B T_n)} \right] \right| \xrightarrow{\mathbf{r}_1 \rightarrow \mathbf{r}_2} \text{finite}, \quad (1.2)$$

where we denote with $[\rho]^n$ the n th power of the pair density matrix. Moreover a *cusp condition* must hold for P as the two particles approach each other [1, 4, 5].

* riccardo.fantoni@scuola.istruzione.it

The same contact value smearing property holds at any temperature T_0 . This feature makes it of fundamental importance not to use the primitive approximation for example in a simulation of an electron proton binary mixture where the divergence of the attractive Coulomb potential between unlike species at contact would inevitably let the fast electrons stick onto the slow protons. In other words quantum statistical physics does not need hard core regularization which is essential in classical statistical physics instead to avoid unlike particles collapse.

In this work we will show how this can be accomplished on a Sphere. We will not give the exact solution for the pair Coulomb density matrix as was done in flat space in Refs. [5–7] but we will give an approximate numerical solution instead. If we were able to find an exact solution of the pair Coulomb density matrix on a sphere we would not need a method to lower the temperature from the classical high temperature limit primitive approximation. Moreover the squaring method can be used only if either an exact solution is known, so that successive squaring allow to reach $T_0/2^n$ temperatures, or we start from very high temperature T_0 and we just want to halve the temperature once. Here we propose to use the path integral discretized in imaginary time with timestep $\tau = 1/k_B T_n$ to reach the temperatures $T_0 = 1/nk_B \tau$ approaching the continuum limit $\tau \rightarrow 0$.

We will only worry about the *end-point approximation* (see section IV.F of Ref. [1]) to the pair Coulomb density matrix. Even if this is exact on a flat space due to the peculiar properties of the Coulomb pair potential [5] it should be regarded just as an approximation on the Sphere.

II. LOWER TEMPERATURE PAIR COULOMB DENSITY MATRIX

We show a method to lower the temperature of the hot Pair Coulomb Density Matrix (PCDM) on a Sphere so to extend the work in flat space of Refs. [5–7] to a curved surface.

We will denote with a Greek index a coordinate component and with a Roman index a particle label. We will adopt Einstein summation convention to tacitly assume a sum over repeated Greek indexes. We distinguish between upper contravariant Greek indexes and lower covariant Greek indexes. Passing between the two is accomplished with a contraction with the metric tensor, as usual.

The metric tensor of the Sphere of radius a is

$$||g_{\alpha\beta}|| = a^2 \begin{pmatrix} 1 & 0 \\ 0 & \cos^2 \theta \end{pmatrix}. \quad (2.1)$$

with $g(\mathbf{r}) = \det||g_{\alpha\beta}|| = a^4 \cos^2 \theta$ and $\theta \in [-\pi/2, \pi/2]$ the polar angle measured from the equatorial plane, so that $\theta = \pi/2$ is the north pole and $\theta = -\pi/2$ is the south pole.

It is important to realize that on a curved surface the two body problem is generally not separable into a center of mass and a relative one body problem. Therefore, in full generality, we will study the position representation $\rho(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}'_1, \mathbf{r}'_2; t)$ of the density matrix $\rho = \exp(-Ht)$, where H is the Hamiltonian operator for the two bodies and t is the imaginary time that in statistical physics is identified with the inverse temperature $\beta = 1/k_B T$ with k_B Boltzmann constant. These are initially at $\mathbf{r}_1$ and $\mathbf{r}_2$ and at an imaginary time t later they are at $\mathbf{r}'_1$ and $\mathbf{r}'_2$.

Therefore, the PCDM on the Sphere will satisfy the Bloch equation

$$\frac{\partial \rho(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}'_1, \mathbf{r}'_2; t)}{\partial t} = \left(\frac{\lambda_1}{\sqrt{g(\mathbf{r}_1)}} \nabla_{1\alpha} \sqrt{g(\mathbf{r}_1)} \nabla_1^\alpha + \frac{\lambda_2}{\sqrt{g(\mathbf{r}_2)}} \nabla_{2\alpha} \sqrt{g(\mathbf{r}_2)} \nabla_2^\alpha - \phi(\mathbf{r}_1, \mathbf{r}_2) \right) \rho(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}'_1, \mathbf{r}'_2; t), \quad (2.2)$$

$$\rho(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}'_1, \mathbf{r}'_2; 0) = \delta(\mathbf{r}_1 - \mathbf{r}'_1) \delta(\mathbf{r}_2 - \mathbf{r}'_2) / \sqrt{g(\mathbf{r}_1) g(\mathbf{r}_2)}, \quad (2.3)$$

where, for particle $i = 1, 2$, $\lambda_i = \hbar^2/2m_i$ with m_i the mass of particle i , $g(\mathbf{r}_i) = a^4 \sin^2 \theta_i$, $\nabla_i = (\nabla_{i1}, \nabla_{i2}) = (\partial/\partial\theta_i, \partial/\partial\varphi_i)$ is the gradient respect to the coordinates $\mathbf{r}_i = (r_i^1, r_i^2) = (\theta_i, \varphi_i)$, δ is a two dimensional Dirac delta function, ρ is the pair density matrix, and ϕ is the Coulomb pair potential.

The Coulomb pair potential for particles moving **on** the surface can be chosen as

$$\phi_{\text{on}}(\mathbf{r}_1, \mathbf{r}_2) = Z_1 Z_2 e^2 / d(\mathbf{r}_1, \mathbf{r}_2), \quad (2.4)$$

where $Z_i e$ is the charge of particle i and for the distance between the two points $\mathbf{r}_1$ and $\mathbf{r}_2$, $d(\mathbf{r}_1, \mathbf{r}_2)$, on the Sphere we can either choose the geodesic distance

$$d_g(\mathbf{r}_1, \mathbf{r}_2) = a \arccos[\sin \theta_1 \sin \theta_2 + \cos \theta_1 \cos \theta_2 \cos(\varphi_1 - \varphi_2)], \quad (2.5)$$

or, viewing the Sphere as embedded in the three dimensional space, the Euclidean distance

$$d_e(\mathbf{r}_1, \mathbf{r}_2) = 2a \sin(d_g/2a). \quad (2.6)$$

For particles living **in** the surface [8] we may choose

$$\phi_{\text{in}}(\mathbf{r}_1, \mathbf{r}_2) = -Z_1 Z_2 e^2 \ln[d_e(\mathbf{r}_1, \mathbf{r}_2)/\ell], \quad (2.7)$$

with ℓ a constant with the dimensions of a distance. We will call ϕ_{on}^g , ϕ_{on}^e , ϕ_{in} the three cases just illustrated.

We will measure energy in units of the Hartree e^2/a_B , with e the charge of the electron and $a_B = \hbar^2/m_e e^2$ Bohr radius, with m_e the mass of the electron. And length in units of the Bohr radius a_B . We will call $\mu_i = m_i/m_e$ the reduced mass of particle i . Temperatures are in units of $\hbar^2/m_e a_B^2 k_B$.

The free particles, $\phi \rightarrow 0$, pair density matrix can be determined from the work of Bastianelli and Corradini [9]. We will call their solution for the single free particle i , $\rho_{i0}(\mathbf{r}_i|\mathbf{r}'_i; t)$. Therefore the pair free density matrix will be

$$\rho_0(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; t) = \rho_{10}(\mathbf{r}_1|\mathbf{r}'_1; t)\rho_{20}(\mathbf{r}_2|\mathbf{r}'_2; t). \quad (2.8)$$

Then our PCDM can be written as

$$\rho(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; t) = \rho_0(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; t)e^{-P(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; t)}, \quad (2.9)$$

where P is the *inter-action* [1].

Aim of this work is to tabulate $P(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; t)$ for the three Coulomb cases illustrated above, P_{on}^g , P_{on}^e , P_{in} . In the hot case, for small $t \ll 1$, for each of these cases, the *primitive approximation* [1]

$$P_{\text{primitive}} \approx t\phi, \quad (2.10)$$

holds.

Therefore, introducing a timestep τ , we can find the PDCM at all subsequent timesteps through the following convolution path integral

$$\begin{aligned} \rho(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; n\tau) &= \int \rho(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}_{1,1}, \mathbf{r}_{2,1}; \tau) \rho(\mathbf{r}_{1,1}, \mathbf{r}_{2,1}|\mathbf{r}_{1,2}, \mathbf{r}_{2,2}; \tau) \cdots \rho(\mathbf{r}_{1,n-1}, \mathbf{r}_{2,n-1}|\mathbf{r}'_1, \mathbf{r}'_2; \tau) \times \\ &\quad \prod_{k=1}^{n-1} \sqrt{g(\mathbf{r}_{1,k})g(\mathbf{r}_{2,k})} d\mathbf{r}_{1,k} d\mathbf{r}_{2,k}, \end{aligned} \quad (2.11)$$

where we denote with $\mathbf{r}_{i,k}$ the position of particle i at timeslice k , $d\mathbf{r} = d\theta d\varphi$, and we choose τ small enough so that

$$\rho(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; \tau) \approx \rho_0(\mathbf{r}_1, \mathbf{r}_2|\mathbf{r}'_1, \mathbf{r}'_2; \tau) e^{-\tau[\phi(\mathbf{r}_1, \mathbf{r}_2) + \phi(\mathbf{r}'_1, \mathbf{r}'_2)]/2} \quad (2.12)$$

$$= \rho_{10}(\mathbf{r}_1|\mathbf{r}'_1; \tau) \rho_{20}(\mathbf{r}_2|\mathbf{r}'_2; \tau) e^{-\tau[\phi(\mathbf{r}_1, \mathbf{r}_2) + \phi(\mathbf{r}'_1, \mathbf{r}'_2)]/2}, \quad (2.13)$$

is a good approximation. We will perform the $4(n-1)$ integrations in Eq. (2.11) through a simple quadrature method.

According to the analysis of Ref. [9] we can further approximate

$$g^{1/4}(\mathbf{r}_i) \rho_{i0}(\mathbf{r}_i|\mathbf{r}'_i; \tau) g^{1/4}(\mathbf{r}'_i) \approx \frac{\mu_i}{2\pi\tau} \exp \left\{ -\frac{\mu_i}{2\tau} \delta_{\alpha\beta} (\mathbf{r}_i - \mathbf{r}'_i)^\alpha (\mathbf{r}_i - \mathbf{r}'_i)^\beta - \tau \frac{V_R(x_i) + V_R(x'_i)}{2} \right\}, \quad (2.14)$$

where $\delta_{\alpha\beta}$ is the Kronecker delta, the normalization $2\pi\tau/\mu_i$ is just the one of a free particle of mass μ_i on a plane and corresponds to the exact path integral performed with an action $\int_0^\tau dt' \mu_i \delta_{\alpha\beta} \dot{\mathbf{r}}_i^\alpha \dot{\mathbf{r}}_i^\beta / 2$, $x_i^2 = \delta_{\alpha\beta} \mathbf{r}_i^\alpha \mathbf{r}_i^\beta$, and V_R is the effective potential due to the curvature of the Sphere, $R = 2M^2$ with $M = 1/a$, namely

$$V_R(x) = -\frac{M^2}{6} - \frac{5(Mx)^2 - 3 + [(Mx)^2 + 3] \cos(2Mx)}{48x^2 \sin^2(Mx)}, \quad (2.15)$$

which is equation (2.32) of Ref. [9].

We may additionally introduce the following exact Feynman-Kac expression for the one free body density matrix at time t

$$g^{1/4}(\mathbf{r}_i) \rho_{i0}(\mathbf{r}_i|\mathbf{r}'_i; t) g^{1/4}(\mathbf{r}'_i) = \langle e^{-S_R} \rangle, \quad i = 1, 2 \quad (2.16)$$

$$S_R = \int_0^t dt' V_R(x_i) \quad (2.17)$$

where $\langle \dots \rangle$ denotes an average over all single particle Gaussian random walks from $\mathbf{r}_i$ to $\mathbf{r}'_i$ in a time t . In Appendix A we give the diagonal part $\rho_{i0}(\mathbf{r}_i|\mathbf{r}_i; t) = \rho_{i0}(\mathbf{0}|\mathbf{0}; t)$ up to orders t^8 . Our Eq. (A1) coincides with the perturbative expansion (3.23) of Ref. [9] for $d = 2$ spatial dimensions.

Even if in general we will be interested in the full $P(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}'_1, \mathbf{r}'_2; t)$ in practice in a many body simulation we may use the *end point approximation* for the inter-action as shown in section IV.F of Ref. [1] where one only needs the diagonal components $P(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; t) = P(d_g(\mathbf{r}_1, \mathbf{r}_2)/a; t)$. Where on a sphere the geodesic distance $d_g(\mathbf{r}_1, \mathbf{r}_2)$ between any two points $\mathbf{r}_1$ and $\mathbf{r}_2$ is bounded from above by πa . Due to the Sphere symmetry, without loss of generality, we may choose $\mathbf{r}_1 = (\pi/2, 0)$ and $\mathbf{r}_2 = (\theta, 0)$, so that $d_g = a(\pi/2 - \theta)$.

On the diagonal we will have

$$\rho(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; t) = \rho(d_g(\mathbf{r}_1, \mathbf{r}_2)/a; t) = \rho_0(d_g(\mathbf{r}_1, \mathbf{r}_2)/a; t) e^{-P(d_g(\mathbf{r}_1, \mathbf{r}_2)/a; t)}, \quad (2.18)$$

we will then tabulate

$$P(m\delta; n\tau) = -\ln \left[\frac{\rho(m\delta; n\tau)}{\rho_0(m\delta; n\tau)} \right], \quad n = 1, 2, 3, \dots, \quad m = 1, 2, 3, \dots, m_{\max} \quad (2.19)$$

for given small τ and δ so that $m_{\max} = \pi/\delta$. For an imaginary time $t_n = n\tau$ this will require a number of $4(n-1)$ quadratures for each m to calculate $\rho(m\delta; n\tau) = \rho(d_g(\mathbf{r}_1, \mathbf{r}_2)/a; t_n) = \rho(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; t_n)$ and $\rho_0(m\delta; n\tau) = \rho_0(d_g(\mathbf{r}_1, \mathbf{r}_2)/a; t_n) = \rho_0(\mathbf{r}_1, \mathbf{r}_2 | \mathbf{r}_1, \mathbf{r}_2; t_n)$ for $m = 1, 2, 3, \dots, m_{\max}$, through the corresponding path integral convolution (2.11). Each convolution requires 4 quadratures over the azimuthal angle $\varphi \in [-\pi, \pi[$ and the polar angle $\theta \in [-\pi/2, \pi/2]$ of each particle. Choosing an angular discretization $\delta_\varphi = 2\delta_\theta$ we will have that each angular integral reduces to a sum over $l = \pi/\delta_\theta$ terms. Then in order to tabulate $P(d_g/a; t_n)$ we need $l^{4(n-1)}$ functions evaluations for each m . This is exponential in n so is only useful for small n . The squaring of the primitive approximation to the PCDM is obtained for $n = 2$ so that $t = 2\tau$. Already for $n = 3$ the calculation becomes extremely computationally demanding at large l . In any case, in a many body simulation the pair-product inter-action is needed at a fixed small t , which determines the discretization error [1]. So one needs to tabulate the PCDM just once, at the beginning of the simulation.

In Table I we show $P(m\delta; n\tau)$ for $a = 1, \mu_1 = \mu_2 = 1, Z_1 = -Z_2 = -1, \tau = 0.01, \delta = 0.3$ and $n = 2$ and compare it to the primitive approximation $n\tau\phi(m\delta)$.

In Fig. 1 we plot the ratio $R(m\delta; n\tau) = P(m\delta; n\tau)/n\tau\phi(m\delta)$ as a function of m for $a = 1, \mu_1 = \mu_2 = 1, Z_1 = -Z_2 = 1, \tau = 0.01, \delta = 0.03$ and $n = 2, l = 30$ and $n = 3, l = 10$. We see how at large particles distance the ratio approaches 1 but at contact it tends to $\approx 1/n$. Therefore we expect that at constant $t = n\tau$ as $n \rightarrow \infty$, in the $\tau \rightarrow 0$ continuum limit, the ratio $R(0) \rightarrow 0$. Moreover the PCDM at particles contact must obey to a cusp condition [5] as discussed in the next section.

TABLE I. Table for $P(m\delta; n\tau)$ for $a = 1, \mu_1 = \mu_2 = 1, Z_1 = -Z_2 = 1, \tau = 0.01, \delta = 0.3$ and $n = 2$. For the angular convolutions in Eq. (2.11) we used a simple quadrature method with $l = 30$. For comparison we also report the values of the Coulomb potential $n\tau\phi(m\delta)$.

III. CUSP CONDITION

On the sphere the cusp condition [1, 4, 5]. can be determined studying the asymptotic behavior as $\mathbf{r}_1 \rightarrow \mathbf{r}_2$ of a vanishing residual energy for the pair-product approximation to the inter-action [1]. On a Sphere as $\mathbf{r}_1 \rightarrow \mathbf{r}_2$ we should compare

$$\left(\frac{\lambda_1}{\sqrt{g(\mathbf{r}_1)}} \nabla_{1\alpha} \sqrt{g(\mathbf{r}_1)} \nabla_1^\alpha + \frac{\lambda_2}{\sqrt{g(\mathbf{r}_2)}} \nabla_{2\alpha} \sqrt{g(\mathbf{r}_2)} \nabla_2^\alpha \right) P(d_g(\mathbf{r}_1, \mathbf{r}_2); t) = -\phi(\mathbf{r}_1, \mathbf{r}_2). \quad (3.1)$$

FIG. 1. We show the plot of the ratio $R(d_g; t) = P_{\text{on}}^g(m\delta; n\tau)/n\tau\phi_{\text{on}}^g(m\delta)$ as a function of $d_g = m\delta$ for $a = 1, \mu_1 = \mu_2 = 1, Z_1 = -Z_2 = 1, \delta = 0.03$ and $\tau = 0.015, n = 2, l = 1, 20, 30$ and $\tau = 0.01, n = 3, l = 10$ with $t = n\tau$. The oscillations observed for $l = 10$ are a numerical artifact of the error in the calculation of the angular convolutions in Eq. (2.11). From the case $n = 2$ we see how already for $l = 30$ the squaring is close to convergence. But for $n = 3$ the case $l = 30$ is prohibitively computationally demanding so we chose $l = 10$.

As $\mathbf{r}_1 \rightarrow \mathbf{r}_2$, $d_g(\mathbf{r}_1, \mathbf{r}_2) \rightarrow 0$ and we are looking at a local property on the sphere so that we can use the result on the tangent plane at the point $\mathbf{r}_1 = \mathbf{r}_2$ namely

$$\lim_{d_g \rightarrow 0} \frac{\partial P_{\text{on}}(d_g; t)}{\partial d_g} = \frac{Z_1 Z_2}{\lambda_1 + \lambda_2}, \quad (3.2)$$

$$\lim_{d_g \rightarrow 0} \frac{\partial P_{\text{in}}(d_g; t)}{\partial d_g} = 0, \quad (3.3)$$

where we used the following expression for the Laplacian in an Euclidean space of dimension d in an isotropic state

$$\nabla_r^2 = \frac{\partial^2}{\partial r^2} + \frac{d-1}{r} \frac{\partial}{\partial r}. \quad (3.4)$$

IV. CONCLUSIONS

We tabulated the pair Coulomb density matrix on the Sphere obtained by lowering the temperature of the classical high temperature primitive approximation through a discretized path integral calculation. As expected we found that the inter-action does not diverge at particles contact as occurs in the primitive approximation. Since we decided to calculate the discretized path integral convolutions with simple quadratures we are constrained to keep far from the continuum limit $\tau \rightarrow 0$. This can be approached efficiently with Monte Carlo integrations [10] instead.

We also derive the cusp condition for the pair Coulomb density matrix on the sphere.
